An AI-Powered Misinformation Detection and Fact-Checking System to Counter the Rise of Far-Right Influence Online

Author: Lance A. Mendoza

I. Introduction

Today, the internet is one of the main ways people get information about news, politics, and current events. Social media platforms like Facebook, X, TikTok, Instagram, and YouTube allow information to spread quickly to millions of users. While this makes it easier for people to stay informed, it also makes it easier for misinformation and false news to spread. Many users read or share information without checking if it is true, which allows misleading content to reach more people. From 2022 to 2026, there has been a noticeable increase in support for right-wing populist movements and far-right groups in different countries. According to Pew Research Center (Wike et al., 2026), support for right-wing populist parties has grown in several Western democracies over the past decade. The report also found that many people who support these movements have less trust in traditional news media and government institutions, making them more likely to believe information from alternative online sources. The Canadian Security Intelligence Service (2025) explains that modern far-right groups are no longer limited to organized hate groups. Instead, they use online communities, social media, podcasts, and messaging apps to spread extremist ideas and misinformation. These groups often use false or misleading information to influence people's opinions, recruit supporters, and create distrust toward governments and minority communities. Yang (2026) also reported that hard-right groups have expanded their influence in the United States while continuing to spread misinformation through online platforms. Since misinformation spreads so quickly online, people need a simple way to check if the information they are reading is accurate. An AI-powered misinformation detection tool can help users identify false or misleading information before they believe or share it. This technology can support responsible internet use and help reduce the spread of harmful misinformation.

II. Problem description

The rise of far-right supporters is closely connected to the spread of misinformation on the internet. Many extremist groups use social media and online platforms to share conspiracy theories, misleading news, and emotionally charged content that attracts attention and encourages people to support their beliefs. According to the Canadian Security Intelligence Service (2025), these groups have become more decentralized and use digital platforms to spread their messages to a larger audience. Another reason misinformation spreads easily is because of social media

algorithms. These algorithms recommend content based on what users watch, like, or share. As a result, users may continue seeing similar political content, even if it is misleading or biased. Over time, this creates situations where people are repeatedly exposed to one point of view while seeing less factual or balanced information. Pew Research Center (Wike et al., 2026) found that distrust in mainstream media has increased among many supporters of right-wing populist movements. This makes it easier for misinformation from unreliable websites or influencers to gain attention. When false information is repeated many times online, some people begin to believe it without checking reliable sources. Yang (2026) reported that hard-right groups have continued to grow their influence while spreading misleading information online, showing that misinformation can have real effects on society. Since many users do not verify information before sharing it, there is a need for technology that helps people recognize misinformation as they browse online.

III. Proposal solution

The proposed solution is an AI-powered misinformation detection and fact-checking tool that works as a browser extension and a mobile application. The tool automatically checks online content, including news articles, social media posts, videos, and blog posts, and compares factual claims with information from trusted, non-biased sources. Its goal is to help users identify misinformation and understand whether the information they are reading is supported by reliable evidence. When it would detect a factual claim, it would compare that claim with information from government agencies, academic institutions, international organizations, and independent fact-checking websites. The tool also checks the credibility of websites by looking at factors such as transparency, source citations, and reliability. It can identify headlines or posts that use emotional or biased language to influence readers. This tool would be designed for students, teachers, journalists, researchers, and anyone who regularly uses the internet. Since it works while users browse online, it would make fact-checking faster and more convenient. Instead of searching for information manually, users can immediately see if a claim has been verified by credible sources.

IV. Conclusion

The increase in far-right supporters from 2022 to 2026 shows how misinformation can influence people's beliefs and political opinions through online platforms. Reports from the Canadian Security Intelligence Service, Pew Research Center, and The Guardian show that far-right groups continue to use social media and online communities to spread misleading information and extremist ideas. As misinformation becomes easier to create and share, internet users need better tools to help them identify what information is true. An AI-powered misinformation detection tool would be a practical and modern technology-based solution because it helps users verify information while browsing the internet. The tool would hopefully encourage users to make informed decisions instead of relying on false or biased information. This can help reduce the spread of misinformation and improve digital literacy among those connected online.
